

We have seen that categories describing the real existence as identified by Heidegger must now be revised in light of a new way being in the world, which is being in the net.

We've dealt with time, space, things, objects, identity and alterity.

Today we discuss about what happens to another existential dimension, language (logos). Logos covers and gather all the nuances that we can find in logos, so discourse, dialogue, opinion, etc.

In order to discuss this topic, we must introduce a preliminary distinction, that is AI, HI (human intelligence) and NI (natural intelligence).

Let's consider what leads natural intelligence: it's basically biological programs, which are stiff, unchangeable, and strictly addressed towards life, based on biological level.

With AI we say the machinical intelligence. Differently from NI, machines are programmed, but their programs are machinable. They're both unchangeable, but one is based on surviving, and the other one is disinterested on it. Machines do not know what death is, so they can emulate or mimic our intelligence, which differently proceeds through projects. Projects are not fixed, but they have the aim that is fixed. The way to get it is keep changing depending on the situation.

What do we share with creatures (with natural intelligence)? We share the biological level, while with AI we share the language.

Language is a word indicating at the same time either the numerical language (the one of programming) and the symbolic language, the one of natural language.

Problem is that language is made of words, but is not the summary of the words itself. It cannot be translated rigidly. Let's see some examples. There is a phrase saying "being that can be understood, is language". We can also see this version "being, that is being understood, is language". In this case, being is language. In the other case, we say that the only part of the being that can be understood is language.

"A man says to Pierino: go to grocery shop, and buy one liter of milk, and if they have eggs buy six". If Pierino is an informatic, he will buy 6 liters of milk, not six eggs. Language is thus ambiguous. One of the pursue of translating language is to disambiguate it, making it univoquos, but the ambiguity of language is not an error, neither something we need to get rid off. In the ambiguity the mistery and possibility of language are contained.

Machines may have text, but they don't have the context, and everything is ambiguous without looking at the context behind and beside the text, as we're not interested only in knowing the meaning of words, but through meaning we try to

identify the sensus.

How machines and we get into a dialogical relationship with machines? First of all, we have to say something. When saying comes to an originary way of saying things, like poetry, or an artistic and not descriptive way of saying something, then machines do not work. Is it depending on the data we insert (like putting better poetry)? No, the problem is that the process make every word sound not specific but flatted for the mediality. The results may be good, but not original. What is the difference between a normal word and a word we use for poetry? That specific word can be used just once in a poetry, and still make sense. Since the use of the word is not connected to the evoking purpose, then we cannot calculate. This is the same with jokes.

This was the first way of communicating with machines. The second one is about listening or hearing, but also in this case we've to remember there're different possibilities: one is that of "sentire", that is a verb we use for hearing and feeling (horen and ge-horen). Differently machines do not pay attention to what we say, they record our words because they've got an interest that is not existential. Other humans listen to us as they have "inter-esse", sharing the same existential situation.

Example: are designed students are mere recorder or listener? They could put a mic, but we have to work around words in an artisanal way. It's another way of communicating, that is answering. We can have different ways of answering: the one of humans, that is answer, so it means to catch other's words, listen to, process it through our interpretation, and then propose another sensus. Differently machines offer replies. The difference is that, no matter who's asking something, the answer is always the same. If I ask to a child living in Liberia what is freedom, his answer would be different from a boy living in NY. If we ask what is freedom to machines, they'll reply the same.

A re-play is something compulsory, that cannot see the other person to which we're talking to, so it's a blind reply.

Let's consider the online discourse, so how we express ourselves online, and what we receive back. The old media, like television or radio, offered broadcasts that is transmitted, from one point to a destination, being a line, with no going back.

What is transmission? It's a flow of images that are transmitted onto a passive screen in a monological (not dialogical) way and without any possibility of answer. What happens when the society of the spectacles encounters the web? Broadcasts become interactive, and therefore spectators may become show themselves.

Touch screen could lead us to the possibility of going beyond mere watching, flooded by content. Action comes from "agere" that means to do, create, handle,

manipulate, move, lead. In german action is hand-lung, while typing would be finger-lung. On the net, our actions don't need our hands, and tasks can be accomplished by using a finger, as typing is enough to get the result done. In doing so, we loose all the other meanings connected to "agere", like creating, as everything is available online as product. Objects disappear in their material existence, the ob-iectum, and also we loose the possibility of living, as digital swarms are dispersive and cannot be stably brought together, as they're loyal only to themselves.

Within the regime of information, being free no longer means acting, but clicking. While we browse the internet we never encounter resistance, as fingers are not capable of actions in the proper sense. They can function as an instrument of command, judgement, and consumer's choices. Through the network, reality ceases to be ready to hand (zu handen heit), and becomes zufingerheit.

Why this is all happening? On one hand, christian rules, according to which the world is placed, allows them to use it as they wish. Is it entrusted in their hands for care? This semantic nuance has major consequences in the way we engage with the world and others.

In the other hand sciences realises these projects of domination over reality, as the project of digitalization. If there is no action but only preferences then there is no real freedom of choice, but only between things that are already given.

This contraction of freedom, while appearing on one side as an advantage or form of help is a way that digital ? use to express power, not by dominating us through violence, but by lightening our ?, and replacing us in everyday's tasks. Even if the regime of information is unable to understand the complexity and depth of our feelings, it's capable to influence our behaviour.

In the infogratic regime human beings are not explicitely controlled and punished, rather surveilled while entertained. Loyalty to the regime is not secured through practices of submission, but through the dependency it creates.

Being in the net, human beings are no longer passive spectators of broadcasts, but transmitter of data and information whose communicative intoxication takes the form of addiction. A regime based on the predominance of information over narratives has important consequences over the political level. Alongside the threat posed by infotainment, democracy is expected by the spread of information, and information/news have only a very narrow margine of relevance in time, and as such they lack the capacity to structure themselves. Reality is thrown into a permanent vortex of immediacy, without diving in stories. It's impossible to dwell in information due to their structural instability, preventing knowledge and experience from unfolding from a broader horizon, or from going deep enough.

Information trains us in an accelerated form of communication where time collapse in a temporal sequence composed of little slices of present, preventing discourse from being structured into coherence.

In this narrow time, it's almost impossible for politics to adopt reasonable decisions, that allow a long range vision in order to be built.

Temporality imposed by the dromographic communication undermines the human capacity to make reasoned choice because pressed by necessity and urgency this long term decisions are replaced with mere rationality. Rational actions propels us over quick solutions, but does not allow reflections. Even political preferences, that we believed are formed over rationally gathered information, are fueled by trolls working by spreading fake news, as well as social bots, which are false accounts pretending to be human beings. News are in this battle, between what is true and plausible. True and plausible leads to things being confused, to post-truth (??).

Example: a few weeks ago the cover of a magazine was published showing an armed soldier smiling and filming a young girl, terrorizing her. Hermeneutics remind us that interpretation may differ in the same image. In this case, the image went viral because of its symbolic power, so eloquent that was impossible to have another interpretation going beyond the evidence. Damage control became necessary, and in the net that in the first place had become the vehicle for spreading this image, is the same web that can be manipulated in order to neutralise it. Net now is an instrument of capturing.

Headlights starts appearing online, having ambassadors of accused state, and affiliated accounts stating the image is fake, and generated by AI.

In this process, one clearly grasps how communication, contained in information, differs from its narrative display. Media are not only means, where facts are received and reported in the form of information, but are also places where those facts are given shape through posts, shares and likes.

The informational noise generated to neutralise the image steers the media system by insinuating doubts. We're not told the photo is false, but we're lead to it by being fueled with doubts. Only at the end, for those who've got patience, a single line appears saying the photo is real, but at that point is too late, as perception has already been taken.

Reality is displaced and diluated, as the point is not to deny it, but ensure that is never completely clear.

Aggravating this condition are all these non-human speakers like chatbots, that manufactures voices in large quantities at almost no cost, shaping the public sentiment by distorting debates. Thanks to political profiling algorithms target to advertisements (??) Dark ads are created for manipulative porpuses ...

Identity, radicalization and the hardening of personal convictions lead to polarization of positions, that works with zeroes and ones, with no nuances in between.

We also have a nullification of possibilities of debating political contents.

This is called tailor-made information based on microtargeting and user tracking does not really inform voters, but deform democracy into a dromocracy by neutralising its capacity of self observation and criticism. Voters, instead of forming their political reasoning through comparison and sharing others positions, are reinforced in their convictions and beliefs, being unknowingly exposed to their conditions.

One of the paradigms governing being in the net respond to a process of continuous implementatino of the same, and in parallel a constant exposure of the other (what is radically different from us).

Another central role played in the electoral campaign is played by memes, which is media reproducing and mutating with great speed. Their structure, requiring no structure, consists of an image accompanied by a short phrase, allowing rapid consumption.

Digital communication privileges images over text because of its immediacy.

However, images do not possess rational grounding.

Justice and democracy are slow and complex systems, built through interpretative balances, sometimes achieved through compromises, and agreements generated through conflicts in dialogues. Informational virality damages its mechanism, forcing them to operate at speeds they cannot sustain. Arguments cannot be portrayed through memes and images, as logical coherence characterising a discourse is alien to the temporal whirlpool through which viral media responds.

Information have its own logic and temporality, and exists beyond truth (responding to post truth). Even fake news has already excercited its full effect before any clarification process begins.

Since information is speedier than truth, run and cannot be caught.
